"Nothing takes place in the world whose meaning is not that of some maximum or minimum."

LEONARD EULER (1707-1783)

INTRODUCTION

Convexity is an important property in optimisation. This is because if a problem is convex then the task of finding a global minimum is reduced to that of finding a local minimum. The importance of finding these minima efficiently in science and engineering has driven the development of software packages, such as cvxpy.

Here we show that an interesting problem in communications has a convex formulation that can be easily implemented computationally using the cvxpy *Python* module. This demonstrates cvxpy as an invaluable tool for both students and researchers in many areas of science and engineering. First let us introduce what convexity means.

Convex functions

If a set C is *convex*, then for any two points $x, y \in C$, any point z along the x, y line must also $\in C$ [1, p.23]. More formally, for $x, y \in C$ and $\theta \in [0, 1]$:

$$\theta x + (1 - \theta)y \in C. \tag{1}$$

A function f, where $f: \mathbb{R}^n \to \mathbb{R}$, is *convex* if $\forall x, y \in \operatorname{dom} f$ and $0 \le \theta \le 1$ [1, p.67]:

$$f(\theta x + (1 - \theta)y) \le \theta f(x) + (1 - \theta)f(y). \tag{2}$$

This means that the function is less than or equal to linear, as shown in Fig. 1. A concave function can be made convex by the operation $f \rightarrow -f$.

Convex optimisation

A convex optimisation problem has three components:

- a convex *objective function* $f_0(x)$,
- m convex inequality constraint functions $f_i(x)$,
- k convex equality constraint functions $g_i(x)$,

where $f,g:\mathbb{R}^n\to\mathbb{R}$ [1, p.141]. We seek an optimum, $x^*\in\mathbb{R}^n$, where $f_0(x^*)$ is a minimum. Formally the problem is defined as:

$$\begin{array}{ll} \text{minimise} & f_0(x) \\ \text{subject to} & f_i(x) \leq 0, \qquad \quad i \in \{1,...,m\} \\ & g_j(x) = 0, \qquad \quad j \in \{1,...,k\}. \end{array} \tag{3}$$

Any local optimum x^* for a convex optimisation problem is also a global optimum [1, pp.138-139], however an optimum may not be unique.

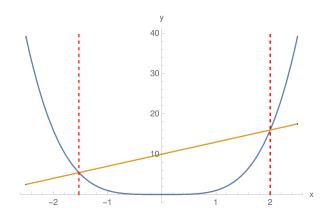

Figure 1. The function $f(x) = x^4$ is plotted in blue. The convexity of this function can be seen by picking any two values of x and noting that f(x) will always lie below or on the chord connecting these two points.

Disciplined convex programming

In order to solve convex optimisation problems, we used cvxpy, a symbolic programming module for *Python*[3]. It uses a set of rules, called *disciplined convex programming* (DCP), to determine whether a function is convex. This is implemented using predefined classes containing functions with their curvature and sign, and using general composition theorems from convex analysis [2]. If DCP rules can be applied then interior point methods guarantee an optimal solution. Interior point methods work by applying Newtons algorithm to sequences of equally constrained problems. The algorithm works by

picking a step and direction to travel in the interior of the feasible convex set, such that the solution progresses towards optimality, for more details on barrier methods and primal-dual methods see [1, p.561].

EXAMPLE: POWER MINIMISATION IN COMMUNICATIONS

To demonstrate the applicability of cvxpy to a real-world example, we consider a system of n transmitters each of power p_i and m receivers, all in 2D Euclidean space[5]. In this problem we are constrained to having a minimum signal-to-interference-plus-noise ratio (SINR or γ) at each receiver

$$\gamma = \frac{S}{I + \sigma} \tag{4}$$

where S is the power of the desired signal, I is the interference power and σ is the background noise at a receiver

How can we minimise the total power consumption, P, of transmitters, yet achieve this minimum SINR, γ_0 , for all receivers? This question is relevant to telecoms companies who want to offer a service at a minimum quality standard. We formulate the problem with a given square path gain matrix, G, background noise level σ , a maximum power constraint $P_{\rm max}$ of each transmitter and the fact that all transmitters must have positive power:

minimise
$$\sum_{j} p_{j}$$
 subject to
$$p_{j} \leq P_{\max}$$

$$p_{j} \geq 0$$

$$\gamma_{i} \geq \gamma_{0}.$$

The desired signal for receiver i is $S_i = G_{ik}p_k$, while the interference at i is $I_i = \sum_{j \neq k} G_{ij}p_j$. However DCP does not allow division of the optimisation variable p_i , as it cannot guarantee curvature, so

$$\gamma_i \ge \gamma_0 \Longleftrightarrow \frac{S_i}{\sigma_i + I_i} \ge \gamma_0, \quad \forall i$$

is rearranged to,

$$S_i - \gamma_0(\sigma_i + I_i) > 0, \quad \forall i$$

which is affine, and hence a DCP function.

Path gain

The path gain G_{ij} represents the proportion of power that reaches receiver i from transmitter j. Supposing that the desired signal to receiver i is from transmitter k, the power received is,

$$p_{ik}^{\text{rec}} = G_{ik} p_k. \tag{5}$$

Denoting the SINR at i by γ_i , we have

$$\gamma_i = \frac{G_{ik}p_k}{\sigma_i + \sum_{j \neq k} G_{ij}p_j} = \frac{S_i}{\sigma_i + I_i}.$$
 (6)

In a physical context, the path gain from transmitter j to receiver i, as shown in Fig. 2, will depend on the distance, d_{ij} between them. Assuming isotropic propagation from each transmitter, the fraction of power from j that reaches i is:

$$G_{ij} = k_i / d_{ij}^{\alpha} \tag{7}$$

where α is the pathloss coefficient and k is a proportionality constant specific to the receiver i. For free space $\alpha=2$, while in urban environments $\alpha\sim3.5$ [4]. Further physical complexities, such as the stochastic effects from Rayleigh fading can be easily incorporated, whilst remaining within the DCP framework.

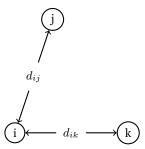

Figure 2. Path lengths between receiver i and transmitters j and k.

Example code

To indicate the brevity of code implementation in cvxpy we show a minimal working example below:

```
import cvxpy as cvx
import numpy as np
# Define variables
k = 1.0
d = np.random.rand(n,n)
d s = 0.5 * (d + d.T)
G = np.zeros((n,n))
G = k / d_s ** 3.5
\# \delta = np.identity(n)
\hat{I}t' = np.identity(n)
\# S = G * \delta
S = G * \hat{I}t'
\# \sigma = 0.1 * np.ones(n)
\ddot{I}\dot{C} = 0.1 * np.ones(n)
\# \gamma = 1.0
\hat{I}_{s} = 1.0
Pmax = 1.0
```

```
# Define optimisation variable
p = cvx.Variable(n)
# Define objective function
obj = cvx.Minimize(
      cvx.sum_entries(p))
# Define constraints
constraints = [p >= 0,
               \# S * p - \gamma * (I * p + \sigma) >= 0,
                S * p - \hat{I} s * (I * p + \ddot{I} C) >= 0,
                p <= Pmax]
# Solve problem and print solution
prob = cvx.Problem(obj, constraints)
prob.solve()
print('Solution status = {0}'.format(prob.status))
print('Optimal solution = {0:.3f}'.format(prob.
    value))
if prob.status == 'optimal':
  for j in range(n):
 print('Power \{0\} = \{1\}'.format(j,p.value[j]))
```

OUTLOOK

The authors hope that this article shows the utility of cvxpy for simple 'toy' problems of real-world relevance. cvxpy can handle problems with up to $\sim 10^3$ transmitters, however this takes $\sim 10^4-10^5 \rm ms$ to run, hence for large real-world problems a faster implementation would likely be required (e.g. C++ based library). However there is obviously a trade off in terms of ease of understanding with these packages.

We believe that cvxpy is an invaluable resource for researchers wanting to test the applicability of convex optimisation in new fields. The module could also be easily incorporated into a course on optimisation, providing students with an accessible environment to practise techniques for convex optimisation. Full code for other communication examples can be found at https://github.com/cvxgrp/cvxpy/tree/master/examples/communications.
